Sensitivity and specificity of the Vimentin/EMA antibody test for invasive cervical carcinoma. In a prospective study, the diagnostic value of the Vimentin/EMA test in the cytologic diagnosis of invasive cervical carcinoma was examined in 65 women who were negative for human papillomavirus (HPV) and 53 women with high-risk HPV infections. Patients were considered at high risk of developing cancer because of a history of cervical intraepithelial neoplasia (CIN) (5 patients) or an increased incidence of cervical cancer in their immediate relatives (11 patients). The findings indicate that the sensitivity and specificity of the Vimentin/EMA test in patients with cervical carcinoma are 88.5% and 100%, respectively, when the cut-off value is set at 9%. In patients with CIN the sensitivity is 77.8% and the specificity 100% (cut-off value 3). When the cytomorphologic diagnosis is negative, the sensitivity is 91.6% and the specificity 100% (cut-off value 2) when the cytomorphologic diagnosis is positive, the sensitivity is 83.3% and the specificity 100% (cut-off value 3). The specificity is 100% in the group of patients with cervical cancer and the sensitivity is 100% in the group of patients with CIN. In the high-risk group the sensitivity and specificity are 80.7% and 100%, respectively (cut-off value 5), and in the group of patients with cervical cancer the sensitivity is 85.7% and the specificity 100% (cut-off value 6).Q: How can I change the tax calculation from country specific to universal?
